

## **Part 1: Stories**

### **Story 1**

I've recently been learning front-end and back-end interaction. With each playing an integral part of web applications I've desired to spend time coding and walking through how axios calls interact with the server and how requests and responses are used. With this integrated into code it expands what an application can do as it can access and process far greater amounts of data stored on the back-end to return and interact with front-end to add to its functionality.

### **Story 2**

Learning how to deploy through cloud platforms like Heroku has become a useful tool in making an application accessible to others, to experience, review and give feedback. Becoming familiar with CircleCI and Rollbar have also been significant tools added to the tool belt. Rollbar has played a valuable role in a recent project to catch errors in the code that users could create within the live environment that are not always visible in development.
